AppSec Research 2012 Athens, Greece

### The OWASP Foundation https://www.owasp.org

# Tricolour Alphanumerical Spaghetti Application Vulnerability Severity Ranking

Do you know your "A, B, Cs" from your "1, 2, 3s"? Is "red" much worse than "orange", and why is "yellow" used instead of "green"? Just what is a "critical" vulnerability? Is "critical" the same as "very high"? How do PCI DSS "level 4 and 5" security scanning vulnerabilities relate to application weaknesses? Does a "tick" mean you passed? Are you using CWE and CVSS? Is a "medium" network vulnerability as dangerous as a "medium" application vulnerability? Can CWSS help?

## Purposes

The presentation today

- ✓ Individual application vulnerabilities
  - ✓ Severity
  - Prioritisation

Not today

- **x** Target level of assurance
- X Application portfolio risk ranking

## Are we speaking the same language?

## Software issue tracking - Bugzilla

- Status (e.g. unconfirmed, new, assigned, reopened, resolved, verified)
- Resolution (e.g. fixed, invalid, wontfix, duplicate, corksforme, duplicate)
- Priority and due date
- Severity measures "impact of a bug"
  - Blocker Blocks development and/or tecting work
  - Critical Crashes, loss of data, severt memory leak
  - Major Major loss of function
  - Normal Regular issue, some loss of functionality under specific circumstances
  - Minor Minor loss of Cunction, or other problem where easy workaround is present
  - Trivial Cosmetic publem like misspelled words or misaligned text
  - Enhancement Request for enhancement

# Event logging severity

- BSD syslog protocol (RFC 3164)
  - 0. Emergency (system is unusable)
  - 1. Alert (action must be taken immediately)
  - 2. Critical (critical conditions)
  - 3. Error (error conditions)
  - 4. Warning (warning conditions)
  - 5. Notification (normal but significant cc. dition)
  - 6. Informational (informational mess. #.s)
  - 7. Debugging (debug-level messay e)
- Common Event Former (CEF)
  - 0 (least) 10 (mos<sup>-</sup> significant)

- Custom ε.g.
  - Fatal (an error that cannot be recovered from)
  - Error
  - Warning (anomalous condition)
  - Informational (non-error events)

## Incident management

## What does [.us].gov have to offer?

# SP800-30 Guide for Conducting Risk Assessments

Risk

- The combination of the likelihood of a threat event's occurrence and its potential adverse impact
- Determine likelihood of threat event
  - Initiation/occurrence
  - Resulting in adverse impacts
- Determine relative impact on the target

## **CERT Secure Coding Standards**

Each rule and recommendation has an assigned **Priority**. Priorities are assigned using a metric based on Failure Mode, Effects, and Criticality Analysis (FMECA) [<u>IEC</u> <u>60812</u>]. Three values are assigned for each rule on a scale of 1 to 3 for

· Severity - how serious are the consequences of the rule being ignored

Value	Meaning	Examples of Vulnerability
1	low	denial-of-service attack, abnormal termination
2	medium	data integrity violation, unintentional information disclosure
3	high	run arbitrary code

· Likelihood - how likely is it that a flaw introduced by ignoring the rule can lead to an exploitable vulnerability

Value	Meaning
1	unlikely
2	probable
3	likely

• Remediation Cost - how expensive is it to comply with the rule

Value	Meaning	Detection	Correction
1	high	manual	manual
2	medium	automatic	manual
3	low	automatic	automatic

The three values are then multiplied together for each rule. This product provides a measure that can be used in prioritizing the application of the rules. These products range from 1 to 27, although only the following 10 distinct values are possible: 1, 2, 3, 4, 6, 8, 9, 12, 18, and 27. Rules and recommendations with a priority in the range of 1-4 are Level 3 rules, 6-9 are Level 2, and 12-27 are Level 1.

#### · Priorities and Levels

Level	Priorities	Possible Interpretation
L1	12, 18, 27	High severity, likely, inexpensive to repair
L2	6, 8, 9	Medium severity, probable, medium cost to repair
L3	1, 2, 3, 4	Low severity, unlikely, expensive to repair

# US-CERT Vulnerability Notes severity metric

- Used in Vulnerability Notes Database
   http://www.kb.cert.org/vuls/
- Method of calculation not publicly available
  - Public knowledge
  - Exploitability (preconditions and ease)
  - Currently being exploited
  - Impact on "the internet"
- Unequal weighting
- Score 0 to 180 (non linear scale)
- If >40, included in US-CERT alerts
- Vulnerability Notes published after 27 March 2012 use CVSS metrics instead

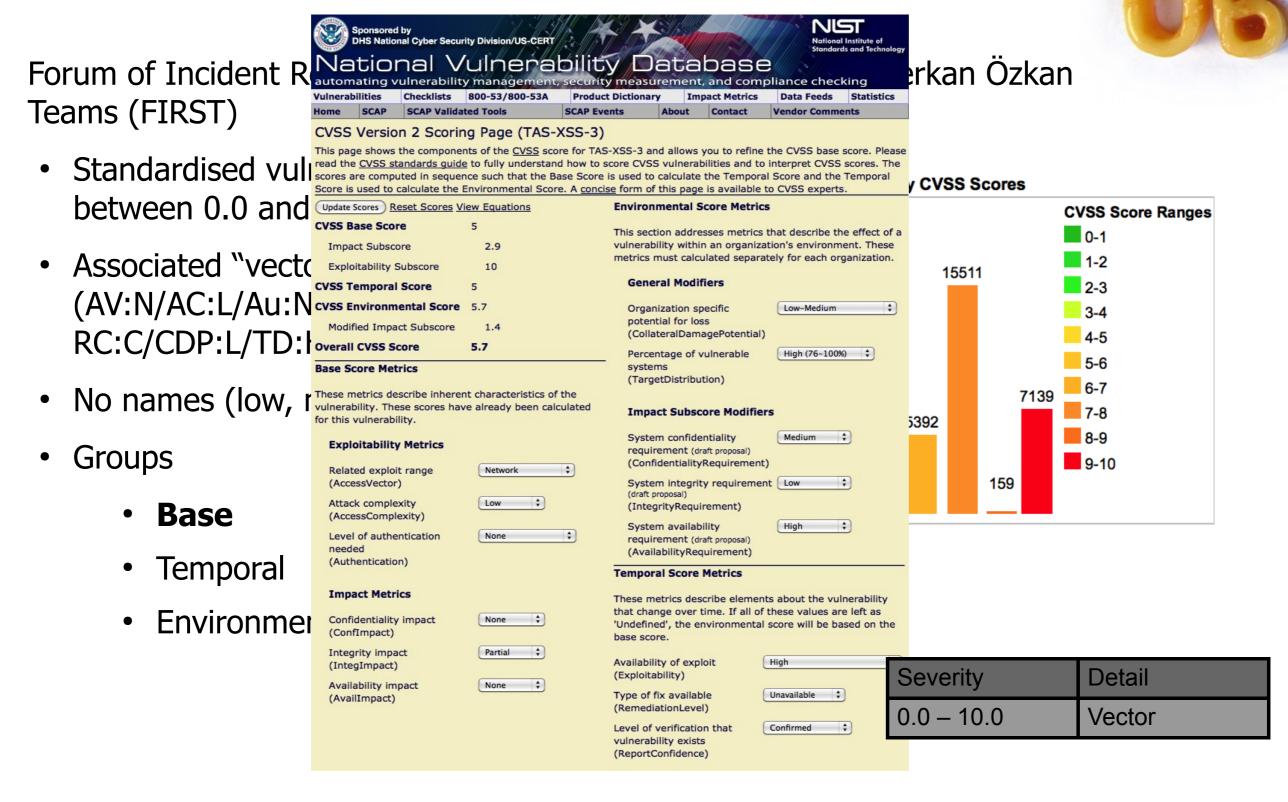

Severity	Include in alerts
41-180	Yes
0-40	No

14

# Common Vulnerability Scoring Standard (CVSS) v2

http://www.first.org/cvss/, http://www.cvedetails.com and http://nvd.nist.gov/cvss.cfm?calculator&adv&version=2

## CxSS

Common Configuration Scoring System (CCSS)

- December 2010
- Use of security configuration settings that negatively affect the security of the software
- Vulnerabilities occur as a result of choosing to configure the software in a particular manner
- Score 0.0 10.0 and vector
- Examples
  - Kernel level auditing disabled
  - Account lockout duration set t less than required minimum
  - FTP service enabled

Common Misuse Scoring System (CMSS)

- July 2012
- Use of a software feature in an unintended manner in a way that provides an avenue to compromise the security of a system
- Vulnerabilities occur as the result of result of providing additional features
- Score 0.0 10.0 and vector
- Examples
  - Bypass file upload anti-virus scanning by changing file extension
  - Attacker can impersonate a valid user
  - User follows link to a spoofed website

15

### Some vendors

## Microsoft severity rating system

Rating	Definition
Critical	A vulnerability whose exploitation could enable the propagation of an Internet worm with little or no user action.
Important	A vulnerability whose exploitation could result in compromise of the confidentiality, integrity, or availability of users' data, or of the integrity or availability of processing resources.
Moderate	A vulnerability whose exploitation is mitigated to a significant degree by factors such as default configuration, auditing, or difficulty of exploitation.
Low	A vulnerability whose exploitation is extremely difficult, or whose impact is minimal.

Severity
Critical
Important
Moderate
Low

### **Tricolour Alphanumerical Spaghetti**

## Microsoft exploitability index system

#### Rating Definition

- 1 Consistent exploit code likely. This rating means that our analysis has shown that exploit code could be created in such a way that an attacker could consistently exploit that vulnerability. For example, an exploit would be able to cause remote code execution of that attacker's code repeatedly, and in a way that an attacker could consistently expect the same results. This would make it an attractive target for attackers, and therefore more likely that exploit code would be created. As such, customers who have reviewed the security bulletin and determined its applicability within their environment could treat this with a higher priority.
- Inconsistent exploit code likely. This rating means that our analysis has shown that exploit code could be created, but an attacker would likely experience inconsistent results, when targeting the affected product. For example, an exploit would be able to cause remote code execution, but may only work 1 out of 10 times, or 1 out of 100 times, depending on the state of the system being targeted and the quality of the exploit code. While an attacker may be able to increase the consistency of their results by having better understanding and control of the target environment, the unreliable nature of this attack makes it a less attractive target for attackers. Therefore, it is likely that exploit code will be created, but it is unlikely that attacks will be as effective as other, more consistently exploitable, vulnerabilities. As such, customers who have reviewed the security bulletin and determined its applicability within their environment should treat this as a material update, but if prioritizing against other highly exploitable vulnerabilities, could rank this lower in their deployment priority.
- Functioning exploit code unlikely. This rating means that our analysis has shown that exploit code which functions successfully is unlikely to be released. This means that it might be possible for exploit code to be released that could trigger the vulnerability and cause abnormal behavior, but it is unlikely that an attacker would be able to create an exploit that could successfully exercise the full impact of the vulnerability. Given that vulnerabilities of this type would require significant investment by attackers to be useful, the risk of exploit code being creating and used is much lower. Therefore, customers who have reviewed the security bulletin to determine its applicability within their environment could prioritize this update below other vulnerabilities within a release.

## Redhat issue severity classification

Level	Description
Critical impact	This rating is given to flaws that could be easily exploited by a remote unauthenticated attacker and lead to system compromise (arbitrary code execution) without requiring user interaction. These are the types of vulnerabilities that can be exploited by worms. Flaws that require an authenticated remote user, a local user, or an unlikely configuration are not classed as critical impact.
Important impact	This rating is given to flaws that can easily compromise the confidentiality, integrity, or availability of resources. These are the types of vulnerabilities that allow local users to gain privileges, allow unauthenticated remote users to view resources that should otherwise be protected by authentication, allow authenticated remote users to cause a denial of service.
Moderate impact	This rating is given to flaws that may be more difficult to exploit but could still lead to some compromise of the confidentiality, integrity, or availability of resources, under certain circumstances. These are the types of vulnerabilities that could have had a critical impact or important impact but are less easily exploited based on a technical evaluation of the flaw, or affect unlikely configurations.
Low impact	This rating is given to all other issues that have a security impact. These are the types of vulnerabilities that are believed to require unlikely circumstances to be able to be exploited, or where a successful exploit would give minimal consequences.

Critical impact
Important impact
Moderate impact
Low impact

# Approved Scanning Vendors (ASVs)

Level	Severity	Description
5	Urgent	Trojan Horses; file read and writes exploit; remote command execution
4	Critical	Potential Trojan Corres; file read exploit
3	High	Limited exploit or read; directory browsing; DoS
2	Medium	Sensitive configuration information can be obtained by hackers
1	Low	Inforn. at on can be obtained by hackers on configuration
	5	able 1 Vulnerability Severity Levels

"High-level vulnerabilities are designated as level 3, 4, or 5"

Level	Severity
5	Urgent
4	Critical
3	High
2	Medium
1	Low

# ASVs (continued)

Security Standards Council

#### Table 2: Vulnerability Severity Levels Based on the NVD and CVSS Scoring

CVSS Score	Severity Level	Scan Results	Guidance
7.0 through 10.0	High Severity	Fail	To achieve a passing scan, these vulnerabilities must be corrected and the environment must be re-scanned after the corrections (with a report that shows a passing scan). Organizations should take a risk-based approach to correct these types of vulnerabilities, starting with the most critical ones (rated 10.0), then those rated 9, followed by those rated 8, 7, etc., until al vulnerabilities rated 4.0 through 10.0 are corrected.
4.0 through 6.9	Medium Severity	Fail	
0.0 through 3.9	Low Severity	Pass	While passing scan results can be achieved with vulnerabilities rated 0.0 through 3.9, organizations are encouraged, but not required, to correct these vulnerabilities.

	Severity	Colour	CVSS2 Base
"Generally, to be considered compliant, a component must r			7.0 – 10.0
that has been assigned a CVSS base score equal to or highe	Medium	Red	4.0 - 6.9
	Low	Green	0.1 – 3.9

### Secunia

#### Term: "Criticality" (Secunia's severity rating)

#### Extremely Critical (5 of 5)

Typically used for remotely exploitable vulnerabilities that can lead to system compromise. Successful exploitation does not normally require any interaction and exploits are in the wild.

These vulnerabilities can exist in services like FTP, HTTP, and SMTP or in certain client systems like email programs or browsers.

#### Highly Critical (4 of 5)

Typically used for remotely exploitable vulnerabilities that can lead to system compromise. Successful exploitation does not normally require any interaction but there are no known exploits available at the time of disclosure.

Such vulnerabilities can exist in services like FTP, HTTP, and SMTP or in client systems like email programs or browsers.

#### Moderately Critical (3 of 5)

Typically used for remotely exploitable Denial of Service vulnerabilities against services like FTP, HTTP, and SMTP, and for vulnerabilities that allow system compromises but require user interaction.

This rating is also used for vulnerabilities allowing system compromise on LANs in services like SMB, RPC, NFS, LPD and similar services that are not intended for use over the Internet.

Less Critical (2 of 5)	Criti	cality	Colour
Typically used for cross-site scripting vulnerabilities and privilege escalation vulnerabilities.	5	Extremely critical	Red
This rating is also used for vulnerabilities allowing exposure of sensitive data to local users.	4	Highly critical	Orange
Not Critical (1 of 5)	3	Moderately critical	Yellow
Typically used for very limited privilege escalation vulnerabilities and locally exploitable Denial of Service	2	Less critical	Greeny-yellow
This rating is also used for non-sensitive system information disclosure vulnerabilities (e.g. remote	1	Not critical	Green
applications).

### Tricolour Alphanumerical Spaghetti

# Qualys Qualysguard

#### Vulnerabilities

Vulnerabilities are design flaws, programming errors, or mis-configurations that make your web application and web application platform susceptible to malicious attacks. Depending on the level of the security risk, the successful exploitation of a vulnerability can vary from the disclosure of information to a complete compromise of the web application and/or the web application platform. Even if the web application isn't fully compromised, an exploited vulnerability could still lead to the web application being used to launch attacks against users of the site.

SEVERITY	LEVEL	DESCRIPTION
	Minimal	Basic information disclosure (e.g. web server type, programming language) might enable intruders to discover other vulnerabilities, but lack of this information does not make the vulnerability harder to find.
	Medium	Intruders may be able to collect sensitive information about the application platform, such as the precise version of software used. With this information, intruders can easily exploit known vulnerabilities specific to software versions. Other types of sensitive information might disclose a few lines of source code or hidden directories.
	Serious	Vulnerabilities at this level typically disclose security-related information that could result in misuse or an exploit. Examples include source code disclosure or transmitting authentication credentials over non-encrypted channels.
	Critical	Intruders can exploit the vulnerability to gain highly sensitive content or affect other users of the web application. Examples include certain types of cross-site scripting and SQL injection attacks.
	Urgent	Intruders can exploit the vulnerability to compromise the web application's data store, obtain information from other users' accounts, or obtain command execution on a host in the web application's architecture.

Information Gathered		Sev	verity	Colour 1	Class	Colour 2	CVSS2 Base

### VeraCode

Veracode Detailed Report Application Security Report for Example Company

Application	WebGoat
Assessed:	

Business Criticality:	Very High	Application Version:	5.0 -
Target Level:	VL4	Published Rating:	DD

#### **Executive Summary**

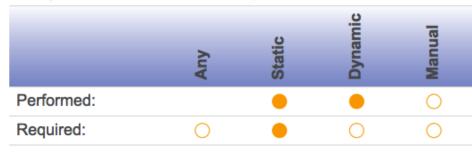

This report contains a summary of the security flaws identified in the application using automated static, automated dynamic and/or manual security analysis techniques. This is useful for understanding the overall security quality of an individual application or for comparisons between applications.

#### Application Business Criticality: BC5 (Very High)

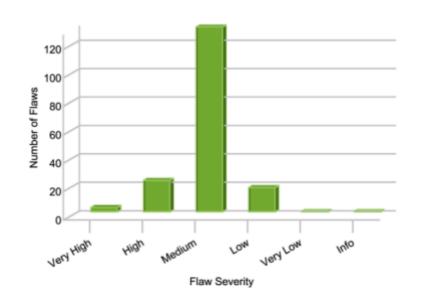

Impacts:Operational Risk (High), Financial Loss (High)

An application's business criticality is determined by business risk factors such as: reputation damage, financial loss, operational risk, sensitive information disclosure, personal safety, and legal violations. The Veracode Level and required assessment techniques are selected based on the policy assigned to the application.

#### Analyses Performed vs. Required

Info

## Some other rating methodologies

# (STRIDE and) DREAD

### STRIDE

Method to help identify threats

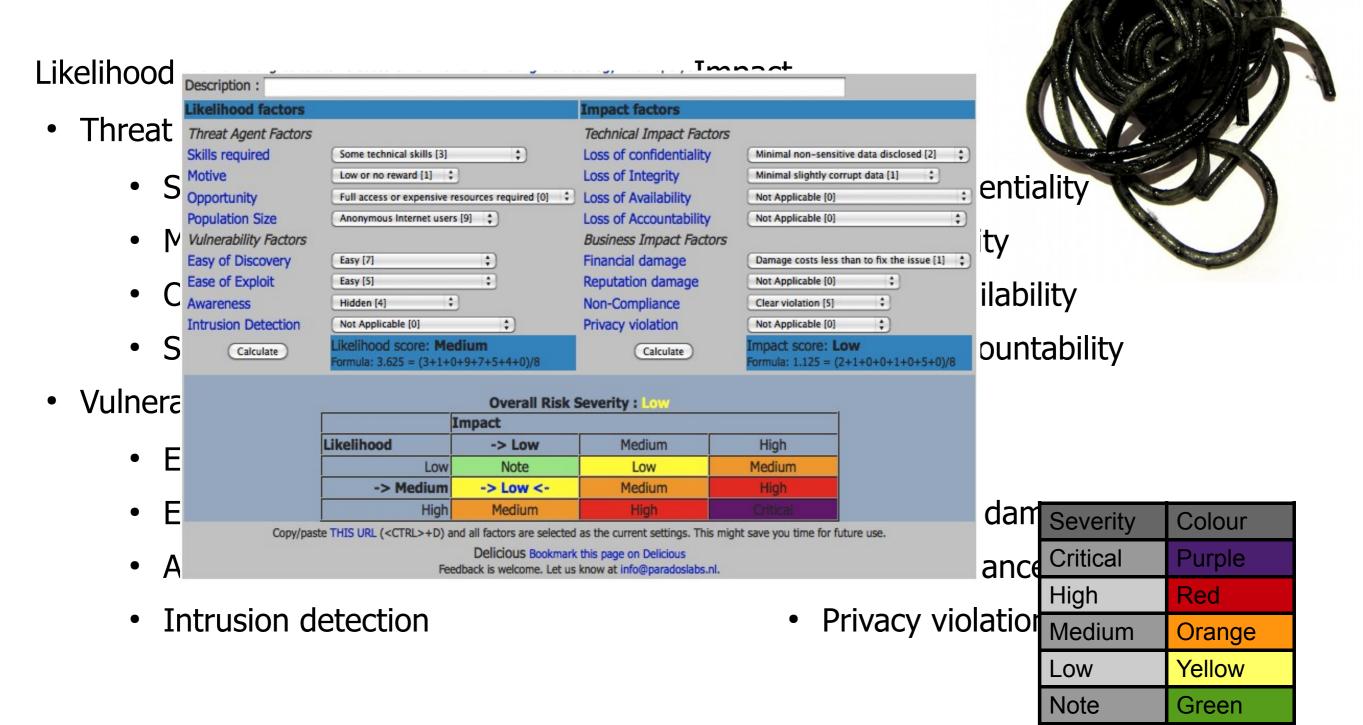

### DREAD

- Classification scheme for quantifying, comparing and prioritising the risk presented by each identified threat
- Calculation (score 1-3 or 1-10 for each):
  - Damage potential
  - Reproducibility
  - Exploitability
  - Affected users
  - Discoverability

Severity
High
Medium
Low

# OWASP Risk Rating Methodology

# CVSS environmental and temporal groups

### Environmental

- Collateral damage potential None, low, low-medium, medium-high, high, not defined
- Target distribution None, low, medium, high, not defined
- Security requirements for each of confidentiality, integrity and availability None, low, medium, high, not defined

Temporal

- Exploitability Unproven, proof of concept, functional, high, not defined
- Remediation level Official fix, temporary fix, workaround, unavailable, not defined
- Report confidence Unconfirmed, uncorroborated, confirmed, not defined

Warning: Vegetarians look away now

## Why it's sometimes even more of a dog's breakfast

# Chained issues

- A sequence of two or more separate weaknesses that can be closely linked together within software
- One weakness, X, can directly create the conditions that are necessary to cause another weakness Y
- Example: XSS via Shared User-Generated Content
  - SVG file type not included in banned file types CWE-184: Incomplete Blacklist
  - Can upload SVG files CWE-434: Unrestricted Upload of File with Dangerous Type
  - Malicious JavaScript code can be executed in user-uploaded SVG file CWE-79: Improper Neutralization of Input During Web Page Generation ('Cross-site Scripting')

## Composite issues

- A combination of two or more separate weaknesses that can create a vulnerability, but only if they all occur all the same time
- One weakness, X, can be "broken down" into component weaknesses Y and Z
- By eliminating any single component, a developer can prevent the composite from becoming exploitable
- Example: Application Worm
  - "Add a Friend" susceptible to CSRF CWE-352: Cross-Site Request Forgery (CSRF)
  - "Add a Friend" susceptible to Type 2 (Stored) XSS CWE-79: Improper Neutralization of Input During Web Page Generation ('Cross-site Scripting')
  - "Add a Friend" usage Increases Exponentially CWE-799: Improper Control of Interaction Frequency

# Aggregation and automation

Channel specific severity ratings

- Vendor vulnerability announcements
- Manual and automated source code analysis
- Manual and automated dynamic analysis
- Operational issue detection (e.g. web application firewalls, configuration monitoring, host intrusion detection, file integrity monitoring systems, event correlation engines, continuous and manual audit processes)
- Notification by customers/clients/citizens
- Export
  - Vulnerability findings exchange
  - Benchmarking

# Counting vulnerabilities

Identity

- Per affected line of code
- Per entry form / page / screen
- Per application

### Generic

- "All"
- "Every form"
- "Every page for authenticated users"

### Groups

- Aggregated
- Chained

### Comparison

- Consistency
- Equality

## Infrastructure vs. application

- CVSS
  - Helps score vulnerabilities in deployed software
  - Repeatable
  - Scores inconsistent where
    - there is missing information
    - there is a desire to achieve a certain value
    - guidance is not followed
  - Doesn't take into account mandatory requirements
- Software
  - Many weaknesses, but not all necessarily vulnerabilities that are also exploitable
  - Scoring based on impact on the system

# Compliance thresholds

"Standards"

- Corporate policies
- CWE/SANS Top 25 Top 25 Most Dangerous Software Errors
- Federal Information Processing Standard (FIPS) 200
- NIST Special Publication 800-37
- OWASP Top 10 Risks
- OWASP Application Security Verification Standard (level?)

Contractual

- PCI SSC (e.g. Data Security Standard)
- Non disclosure agreements
- Contractual clauses and SLAs

Legislation and regulations

Rating

- Binary choice?
  - Pass
  - Fail
- Not quite black and white
  - Degree of confidence
  - Coverage
- Accepted non-compliance
  - Emergency
  - Business as usual
  - Ignored

## Read the label

  - Target Distribution
- Exploitability

## CWRAF

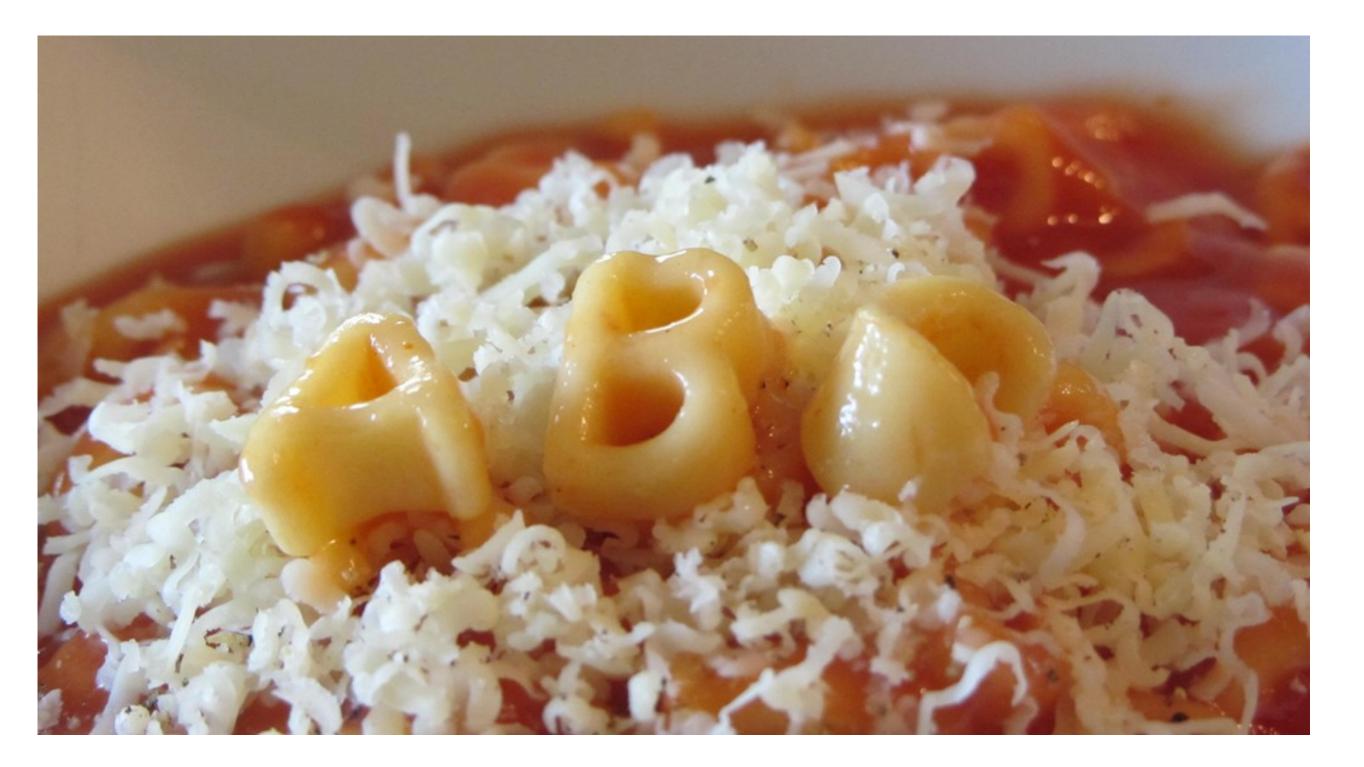

Common Weakness Risk Analysis Framework (CWRAF)

- Business value context
- Technical impact scoresheets
  - 1 -10 Modify data
  - 1 -10 Read data
  - 1 -10 DoS: unreliable execution
  - 1 -10 DoS: resource consumption
  - 1-10 Execute unauthorised code or commands
  - 1-10 Gain privileges / assume identity
  - 1 -10 Bypass protection mechanism
  - 1 -10 Hide activities

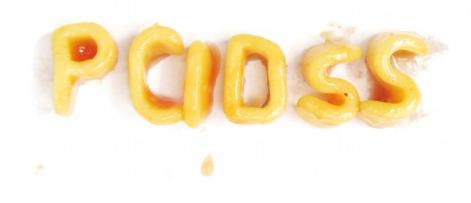

## E-commerce drivers

## Requirement 6.2

PCI Security Standards Council	_
-----------------------------------	---

Requirement	Guidance
<b>6.2</b> Establish a process to identify and assign a risk ranking to newly discovered security vulnerabilities.	The intention of this requirement is that organizations keep up-to-date with new vulnerabilities that may impact their environment.
Notes: Risk rankings should be based on industry best practices. For example, criteria for ranking "High" risk vulnerabilities may include a CVSS base score of 4.0 or above, and/or a vendor-supplied patch classified by the vendor as "critical," and/or a vulnerability affecting a critical system component. The ranking of vulnerabilities as defined in 6.2.a is considered a best practice until June 30, 2012, after which it becomes a requirement.	<ul> <li>While it is important to monitor vendor announcements for news of vulnerabilities and patches related to their products, it is equally important to monitor common industry vulnerability news groups and mailing lists for vulnerabilities and potential workarounds that may not yet be known or resolved by the vendor.</li> <li>Once an organization identifies a vulnerability that could affect their environment, the risk that vulnerability poses must be evaluated and ranked. This implies that the organization has some method in place to evaluate vulnerabilities and assign risk rankings on a consistent basis. While each organization will likely have different methods for evaluating a vulnerability and assigning a risk rating based on their unique CDE, it is possible to build upon common industry accepted risk ranking systems, for example CVSS. 2.0, NIST SP 800-30, etc.</li> </ul>
	Classifying the risks (for example, as "high", "medium", or "low") allows organizations to identify and address high priority risk items more quickly, and reduce the likelihood that vulnerabilities posing the greatest risk will be exploited.

## Requirement 6.5.6

PCI	Security The Standards Council —

Requirement	Guidance
<b>6.5</b> Develop applications based on secure coding guidelines. Prevent common coding vulnerabilities in software development processes, to include the following:	The application layer is high-risk and may be targeted by both internal and external threats. Without proper security, cardholder data and other confidential company information can be exposed, resulting in harm to a company, its customers, and its
<b>Note</b> : The vulnerabilities listed at 6.5.1 through 6.5.9 were current with industry best practices when this version of PCI DSS was published. However, as industry best practices for vulnerability management are updated (for example, the OWASP Guide, SANS CWE Top 25, CERT Secure Coding, etc.), the current best practices must be used for these requirements.	reputation. As with all PCI DSS requirements, Requirements 6.5.1 through 6.5.5 and 6.5.7 through 6.5.9 are the <i>minimum</i> controls that should be in place. This list is composed of the most common, accepted secure coding practices at the time that this version of the PCI DSS was published. As industry accepted secure coding practices change, organizational coding practices should likewise be updated to match.
	The examples of secure coding resources provided (SANS, CERT, and OWASP) are suggested sources of reference and have been included for guidance only. An organization should incorporate the relevant secure coding practices as applicable to the particular technology in their environment.

<b>6.5.6</b> All "High" vulnerabilities identified in the vulnerability identification process (as defined in PCI DSS Requirement 6.2).	Any high vulnerabilities noted per Requirement 6.2 that could affect the application should be accounted for during the development phase. For example, a
<i>Note</i> : This requirement is considered a best practice until June 30, 2012, after which it becomes a requirement.	vulnerability identified in a shared library or in the underlying operating system should be evaluated and addressed prior to the application being released to production.

# Risk ranking of vulnerabilities

- Avoid using the terms "low", "medium" or "high"
- Triage
  - "high"
  - "not high"
  - out of scope
- Prioritise but flag all the issues that can impact on the security of the cardholder data environment

## Build your own

# The most important points

### Clarity

- Make it understandable
- Define terminology
- Avoid numbers post calculation
- Don't get hung up on precise names
- Scoring is not that accurate, so think about fuzzy ranges
- Train users

#### Environment-specific

- Technical
- Business

#### Consistency

- Differentiation (spread of scores)
- Reproducible

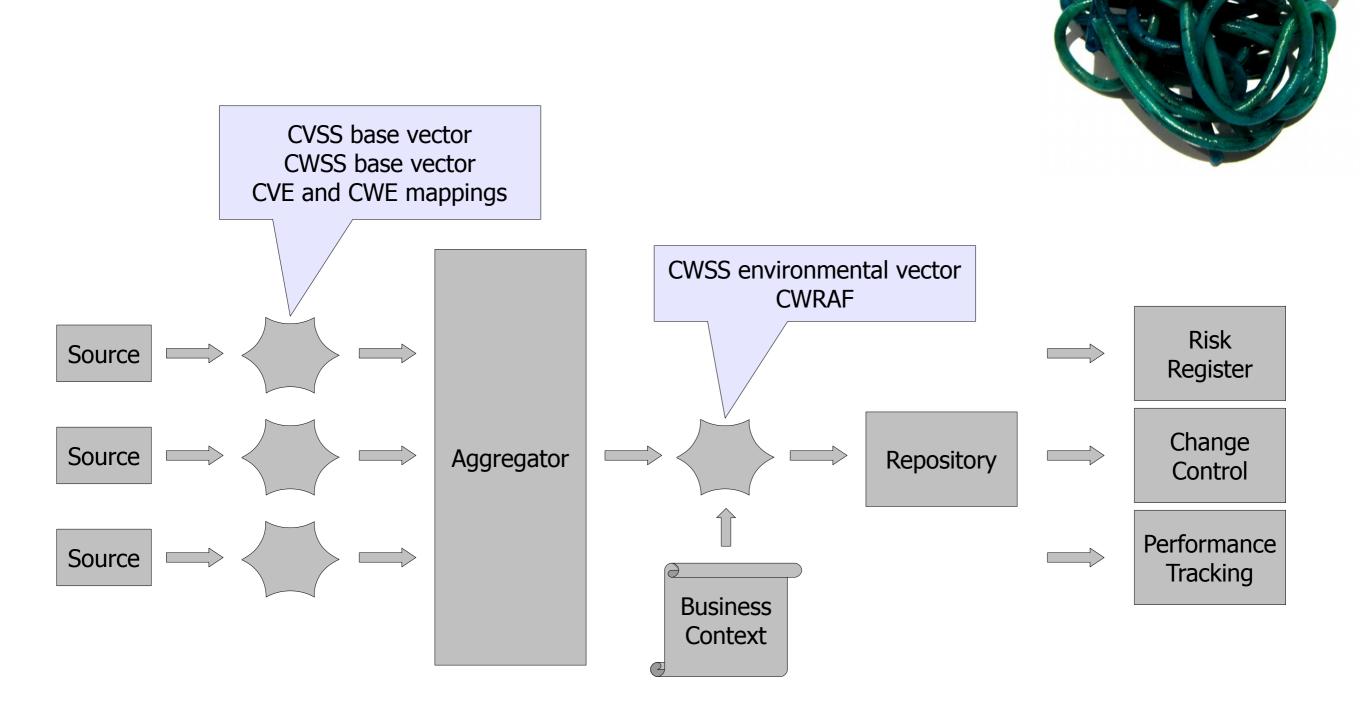

#### Test the scheme

- Test plan
- Edge cases
  - Unconfirmed vulnerability
  - Unexploitable vulnerability
  - Exploitable but negligible impact
  - Exploitable but extremely improbable

#### Prepare for / enable automation

- Identification
- Interoperability
- Mappings (one to many)
- Level of confidence
- Time dependent data
- Out-of-scope results

A proposed risk assessment framework

## Engagement with others

As the recipient (e.g. development manager, application owner, business manager)

- Define the objectives of the verification activity
- Discuss in advance what pass or fail means
- Understand the scoring/rating methodology being used, whether this has changed and especially what impact target is being assumed
- If CVSS is used, insist upon having both the score and the vector
- Insist upon more than a generic description of the vulnerability and a severity rating

As a provider (e.g. design/code reviewer, pen test company, ASV, software analysis vendor)

- Understand the client's business and risks
- Ask the client if they have a preferred rating methodology
- Find out what the client's objectives are
- Know what threshold(s) the client will be sensitive to
- Be open about the ranking process used
- Use CWE identifiers in findings
- Consider CCSS, CMSS and CWSS too
- Provide recommendations and discuss mitigating measures and considerations

## Conclusion

## Assess yourself

- 1. Is "red" much worse than "orange"?
- 2. Why is "yellow" used instead of "green"?
- 3. Just what is a "critical" vulnerability?
- 4. Is "critical" the same as "very high"?
- 5. How do PCI DSS "level 4 and 5" security scanning vulnerabilities relate to application weaknesses?
- 6. Does a "tick" mean you passed?
- 7. Are you using both CWE and CVSS?
- 8. Is a "medium" network vulnerability as dangerous as a "medium" application vulnerability?
- 9. Can CWSS help?

10. Does risk ranking equate to prioritisation?

- 1. Not necessarily
- 2. Green could suggest no risk
- 3. It depends on your own definition
- 4. (as above)
- 5. Your "Risk Ranking Process" created to meet PCI DSS requirement 6.2 needs to define this
- 6. Not always
- 7. Yes
- 8. It might be it depends what you mean by "danger" – but this should be a comparison of likelihood & impact
- 9. Yes

#### 10.No, but they are related

#### Tricolour Alphanumerical Spaghetti
